## Problem 1: HCL (10 points)

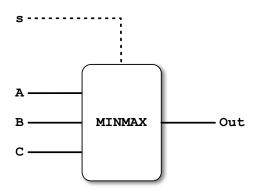

Please write down the HCL expressions for the following signals (HINT: you can refer to the **Section 4.2.2** in the CSAPP book).

**EXAMPLE**: a signal EQ which shows if two input a and b are equal: bool EQ = (a&&b) || (!a && !b);

1. The HCL expression for a signal **IMPLIES**. "a **IMPLIES** b" for bool a and bool b means that if a is true, then b must also be true. The truth table is given below. (4')

a	b	a IMPLIES b
T	T	Т
T	F	F
F	T	Т
F	F	Т

2. The HCL expression for a word-level signal MINMAX which takes three word (word A, word B, word C) and a Boolean selector (bool s) as inputs. When s is true, MINMAX outputs the minimum value of the given three words. When s is false, MINMAX outputs the maximum value of these words. The diagram of MINMAX is showed below. (6')

#### Problem 2: Y86 (18 points)

```

0x016c: 00
                                     halt
```

- 1. Please fill in the blanks within above Y86 binary and assembly code. (2'\*7=14')
- 2. What the instruction "0x012a: andq %rdx, %rdx" and "0x012c: jle End" want to protect? (2') What problems that function My\_Operation may cause without such two instruction? (2')

#### **Problem 3: Memory Allocation (16 points)**

There are some **unallocated memory** and **heap**, as shown below. heap is organized as a sequence of **contiguous** allocated and free blocks. **Allocated** blocks are shaded, and **free** blocks are blank (each block represents 1 word = 4 bytes). **Headers** and **footers** are labeled with the number of bytes and allocated bit. The allocator maintains **double-word** alignment. You are given the execution sequence of memory allocation operations (i.e., malloc() or free()) from 1 to 5.

			<b>V</b> P1						
8/0	8/0	24/1					24/1	16/0	
	<b>↓</b> P2								
	16/0	16/1			16/1	16/0			16/0
	VP3 Vbrk								
16/1			16/1						

- 1.P4 = malloc(5)
- 2.free(P1)
- 3.free(P2)
- 4.P5 = malloc(6)
- 5.P6 = malloc(7)

Please answer the questions below. Assume that **immediate coalescing** strategy and **splitting free blocks** are employed.

- 1. Assume **first-fit** algorithm is used to find free blocks. Please draw the **final** status of memory and mark with block size in headers and footers after the operation sequence  $(1\sim5)$  is executed (4').
- 2. Assume **next-fit** algorithm is used to find free blocks. Please draw the **final** status of memory and mark with block size in headers and footers after the operation sequence (1~5) is executed (4').(note: For next-fit algorithm, you can refer to the **Section 9.9.7.** in the CSAPP book)
- 3. Instead of executing operation sequence (1~5), we want to execute an operation 6:
  P7 = malloc(13). Please explain what malloc operation may do (1') and draw the final status of memory and mark with block size in headers and footers. (2')
- 4. Please calculate internal fragmentations caused by operation 1 ,4 and 5(P4,P5,P6) (3'). As we can see, there are many fragmentations in the heap. Please provide at least one optimization to decrease the internal fragmentations. (2') (Hint: you can consider whether the headers and footers are necessary in allocated block)

#### Problem 4: Optimization (22 points)

```
1 typedef struct {
                             /* number of element in this array */
2
      long len;
      double *data;
                             /* raw data */
4 } fp arr;
                             /* floating point array */
6 long get len(fp arr arr) {
      return arr.len;
8 }
9
10 double * ele at(fp arr arr, long idx) {
      return &(arr.data[idx]);
11
12 }
13
14 void do arr(fp arr arr1, fp arr arr2, fp arr arr3, double *res) {
      for (long i = 0; i < get len(arr1); i++) {
15
         *ele at(arr3, i) = *ele at(arr1, i) * *ele at(arr2, i);
16
         *res += *ele at(arr1, i) * *ele at(arr2, i);
17
18
19 }
20 void do arr v2(double *arr1, double *arr2, double *arr3, long len) {
      for (long i = 0; i < len; i++)
21
         arr3[i] = arr1[i] * arr2[i];
23 }
24
             $0, %eax
      movl
25 .L3:
26
      movsd (%rdi,%rax,8), %xmm0
27
      mulsd
              (%rsi,%rax,8), %xmm0
28
      movsd
              %xmm0, (%rdx, %rax, 8)
29
      addq
             $1, %rax
30
      cmpq
             %rax, %rcx
31
              .L3
      jne
```

 Billy writes a function do\_arr as shown in above. Please help him improve the performance by rewriting the function do\_arr with a combination of at least 4 different optimizations you have learned in class. Comment briefly on the optimizations. (2'\*4=8')

NOTE: your optimizations cannot change the functionality of do arr.

2. Suppose the optimizations you proposed in the first question can speedup the performance of do\_arr to **5X** and do\_arr takes 40% of the total time of some \_A\_卷 总\_\_12\_页 第\_8\_页

- program **A**. Please compute the speedup of program **A** after the optimization. (**HINT**: you may refer to 1.9.1 Amdahl's Law) (3')
- 3. Billy decides to simplify the do\_arr function to do\_arr\_v2 (see **line 20-23**). The assembly of do\_arr\_v2 is given in **line 24-31**. Please abstract the operations as a data-flow graph. **Drawing rules**:
  - a) All registers (except %xmm0), operations that appear in line 26-29 and the data flow between them are required to be drawn. (5')
  - b) Conditional data dependency when load and store address match should also be considered and drawn in dashed line. (2')

You may refer to Figure 5.36 (a) in the CSAPP book.

4. Suppose arr1 and arr2 are double arrays of length 10000, and their memory range do NOT overlap. The latency and issue time characteristics of reference machine operations are provided below. What CPE of calling do\_arr\_v2(arr1, arr2, arr1+1, 9999) would you expect? Please explain your answer. (4')

operation	inte	eger	double-precision			
operation	latency	issue	latency	issue		
addition	1	1	3	1		
multiplication	3	1	5	1		
load/store	3	1	3	1		

#### **Problem 5: Processor (34 points)**

Here is a program and part of its assembly code written in Y86:

```
void calc(int* array, int size) {
                                   Loop:
   int sum = 0;
                                      mrmovq (%rdi), %r10 // %r10 = *a
   int* a = array;
                                              %r10, %r10
                                      andq
   for (; size>0 ; size--) {
                                      jle
                                              L2
                                                            // if (%r10 > 0)
                                              $1, %rax
       if (*a > 0) {
                                      iaddq
                                                           //
                                                                  sum++
          sum += 1;
                                   L2:
                                              $1, %rax
                                      iaddq
                                                           // sum++
       }
                                                           // a++
       sum += 1;
                                      iaddq
                                              $4, %rdi
                                              $-1, %rdx
                                                           // size--
      a++;
                                      iaddq
   }
                                             Loop
                                      jg
                                      halt
}
```

- 1. Now run the program on unmodified **PIPE** implementation with input **{-1, 2, 3, 4, 5}** stored in array and size = 5.
  - a. Show **all hazards** in the **given assembly code** and **how many bubbles** will be inserted for **each** kind of hazard. (6')
  - b. Calculate the **CPI** of the **given assembly code**. **NOTE:** calculate the total cycles from the **first stage** of the first instruction to the **last stage** of the last instruction, and the total number of instructions is the **number of instructions that are actually executed**. (2')

Here we will implement a new instruction to reduce the overhead of **misprediction**: conditional redo, **credoxx**, with following encoding:

	Byte	0	
credoxx		E	Fn

Name	Value (hex)	Meaning			
ICREDOXX	E	Code for credoxx instruction			

This instruction (for example, credole) will repeat the next instruction if the condition is satisfied, which causes the next instruction be executed twice.

2. Please list the **detection conditions** like Figure 4.64 and **new control action** like Figure 4.66 in the following situations. **NOTE: DO NOT** consider the **combinations** of hazards here. (1'\*8)

```
__A__卷 总___12__页 第<u>__10</u>__页
```

a. What if the credoxx is **NOT-TAKEN**? (**NOTE**: **NOT\_TAKEN** means the next instruction would not be repeated.)

Condition	Trigger						
	<pre>E_icode == ICREDOXX &amp;&amp; [1]</pre>						
credoxx not-taken	Pipeline register						
Credoxx Not-taken	F	D	E	M	W		
	[2]	[3]	[4]				

b. What if the credoxx is **TAKEN**? (**HINT:** Recall the usage of stall)

Condition	Trigger						
	<pre>E_icode == ICREDOXX &amp;&amp; [5]</pre>						
credoxx taken	Pipeline register						
Credoxx taken	F	D	E	M	W		
	[6]	[7]	[8]				

- 3. Please rewrite the **given part** of assembly code using **credoxx**. Using the given input, **how many cycles do you save** compared to question 1? (4'+2')
- 4. There will be new combination of pipeline hazards due to credoxx TAKEN.
  - a. Please draw the combination like **Figure 4.67**. (2')
  - b. Show how to handle it correctly. (4')

Pipeline register								
F	D	E	M	W				
[1]	[2]	[3]	[4]	normal				

5. Please provide the **increased or modified HCL** code in **PIPE** implementation of **F\_stall**, **D\_bubble** and **D\_stall** logic caused by **credoxx** instruction. (3')

For example:

6. According to Figure 4-57, when F stage is stalled, the f\_pc may still receive value from M\_valA or W\_valM, which may change the repeated instruction to another one. Can credoxx work correctly in this situation? Why? (HINT: think about what kind of instructions will generate M\_valA and W\_valM and pass them to f\_pc.) (3')
